pembrolizumab (KEYTRUDA°) in Hodgkin lymphoma with no further treatment options

Inadequate premarketing assessment

NOT ACCEPTABLE

An evaluation just as inadequate as that of *nivolumab* in Hodgkin lymphoma, mainly based on a single, short, non-comparative trial using surrogate endpoints. *Pembrolizumab* has many, sometimes serious, adverse effects.

KEYTRUDA° - *pembrolizumab* powder for concentrate for solution for intravenous infusion, and concentrate for solution for intravenous infusion

- **50 mg** of *pembrolizumab* powder, to be dissolved to obtain a 25 mg/ml solution, then diluted in an IV infusion bag
- **100 mg** of *pembrolizumab* as a 25 mg/ml solution, to be diluted in an IV infusion bag

■ **immunostimulant; PD-1 inhibitor**

■ **New indication:** "*relapsed or refractory Hodgkin lymphoma after failure of autologous stem cell transplant and brentuximab vedotin, as monotherapy in adult patients*". [EU centralised procedure]

In patients with relapsed or refractory Hodgkin lymphoma who have already received an autologous haemopoietic stem cell transplant, no drugs, including *brentuximab vedotin*, have been shown to prolong survival. After failure of autologous transplantation and *brentuximab vedotin*, the harm-benefit balance of the immunostimulatory anti-PD-1 antibody *nivolumab* is unfavourable as of early 2018, because its effect on clinical endpoints has barely been evaluated and due to its many and severe adverse effects (1).

Another immunostimulatory anti-PD-1 antibody, *pembrolizumab* (Keytruda°, Merck Sharp & Dohme), has been authorised in the European Union for patients with Hodgkin lymphoma after failure of an autologous haemopoietic stem cell transplant and *brentuximab vedotin*; or after failure of *brentuximab vedotin* alone when autologous haemopoietic stem cell transplantation is not an option (2).

The clinical evaluation for *pembrolizumab* in this situation, at a dose of 200 mg every 3 weeks, is focused on a single non-comparative trial in 210 adults. After a median follow-up of 10 months, 4 patients had died. As *pembrolizumab* was not compared with appropriate symptomatic care and the follow-up was so short, it is impossible to determine whether this drug prolongs survival. 22% of the patients exhibited a "complete" response, based on radiological assessment (2,3).The duration of the complete responses was not specified in the documents identified by our literature search.

The known adverse effects of *pembrolizumab* are often of immunological origin: rash, including Stevens-Johnson syndrome and toxic epidermal necrolysis, endocrine disorders (thyroid disease, hypophysitis, diabetes), hepatitis, pneumonitis, diarrhoea, colitis, neurological disorders (including encephalitis and Guillain-Barré syndrome), nephritis, uveitis, myositis, transplant rejection; and also sarcoidosis and severe infusion reactions (2,4,5). In a pooled analysis of the trial referred to above, in 210 patients, and a non-comparative trial of a different dose of *pembrolizumab* in 31 patients with Hodgkin lymphoma, a severe *pembrolizumab*-related adverse effect was reported in 12% of patients (3).

A total of 23 patients in these two non-comparative trials underwent allogeneic haemopoietic stem cell transplantation after receiving *pembrolizumab* (3). Seven of them had a complication, including six with graft-versus-host disease. One case was fatal (2,3). It is probable that *pembrolizumab* had a role in these reactions due to its immunostimulatory action. *Nivolumab* is thought to carry the same risk (1).
